# **Class 7: Machine Learning**

Chloe Wong (PID: A16893383)

Today we are going to learn how to apply different machine learning methods, beginning with clustering:

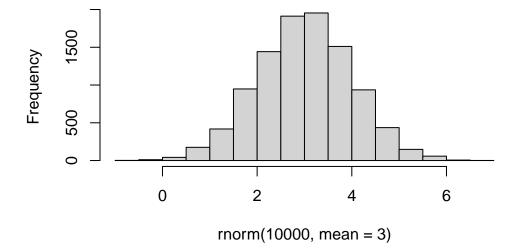

The goal here is to find groups/clusters in your input data.

First I will make up some data with clear groups. For this I will use the rnorm() function:

### rnorm(10)

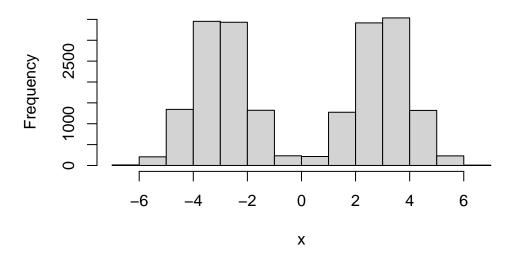

```
hist(rnorm(10000, mean = 3))
```

## Histogram of rnorm(10000, mean = 3)

```
n <- 10000
x <- c(rnorm(n, -3), rnorm(n, +3))
hist(x)</pre>
```

# Histogram of x

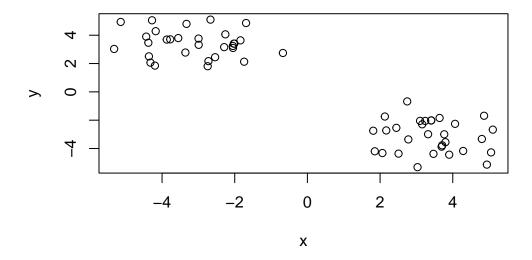

```
n <- 30
x <- c(rnorm(n, -3), rnorm(n, +3))
y <- rev(x)

z <- cbind(x,y)
head(z)</pre>
```

```
x y
[1,] -2.723726 2.169675
[2,] -2.024667 3.405520
[3,] -1.741238 2.131105
[4,] -4.361547 2.507584
[5,] -2.667583 5.102311
[6,] -5.318701 3.031132
```

```
plot(z)
```

Use the kmeans() function setting k to 2 and nstart=20

Inspect/print the results

- Q. How many points are in each cluster? There are 60 points in each cluster.
- Q. What 'component' of your result object details cluster size? cluster assignment/membership? cluster center? Answered below.
- Q. Plot x colored by the kmeans cluster assignment and add cluster centers as blue points. Answered below.

```
km <- kmeans(z, centers = 2)
km</pre>
```

K-means clustering with 2 clusters of sizes 30, 30

### Cluster means:

x y 1 -3.125852 3.408706 2 3.408706 -3.125852

#### Clustering vector:

Within cluster sum of squares by cluster:

[1] 65.44407 65.44407

(between\_SS / total\_SS = 90.7 %)

Available components:

[1] "cluster" "centers" "totss" "withinss" "tot.withinss"

[6] "betweenss" "size" "iter" "ifault"

Results in kmeans object km

#### attributes(km)

\$names

[1] "cluster" "centers" "totss" "withinss" "tot.withinss"

[6] "betweenss" "size" "iter" "ifault"

\$class

[1] "kmeans"

Cluster size?

#### km\$size

[1] 30 30

Cluster Assignment/membership?

#### km\$cluster

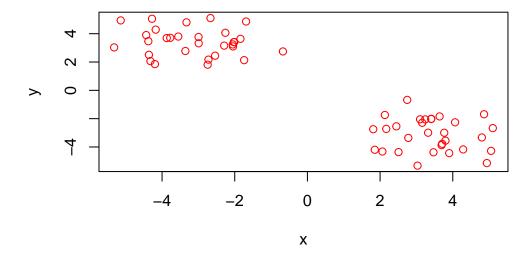

Cluster center?

#### km\$centers

```
x y
1 -3.125852 3.408706
2 3.408706 -3.125852
```

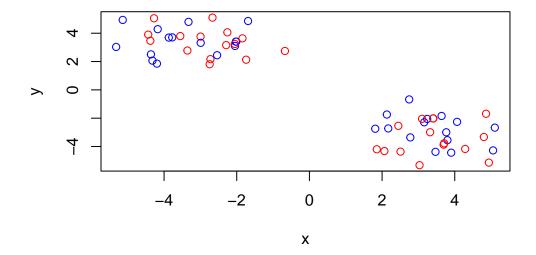

Q. Plot x colored by the kmeans cluster assignment and add cluster centers as blue points.

```
plot(z, col= "red")
```

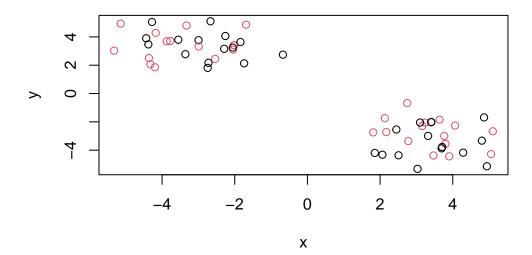

R will re-cycle the shorter color vector to be the same length as the longer number od data points) in z

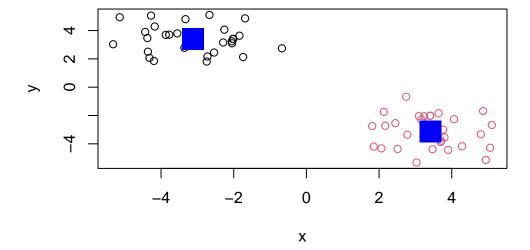

```
plot(z, col= c("red","blue"))
```

## plot(z, col=c(1,2))

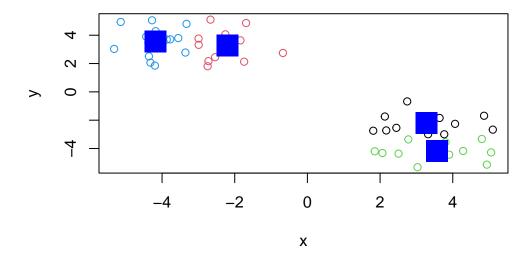

```
plot(z, col=km$cluster)
points(km$centers, col = "blue", pch = 15, cex = 3)
```

Q. Can you run kmeans and ask for 4 clusters please and plot the results like we have done above?

```
km4 <- kmeans(z, centers = 4)
plot(z, col=km4$cluster)
points(km4$centers, col = "blue", pch = 15, cex = 3)</pre>
```

## ##Hierarchical Clustering

Let's tke our same made-up data  ${\bf z}$  and see how h clust works.

First we need a distance matrix of our data to be clustered.

```
d <- dist(z)
hc <- hclust(d)
hc</pre>
```

## Call:

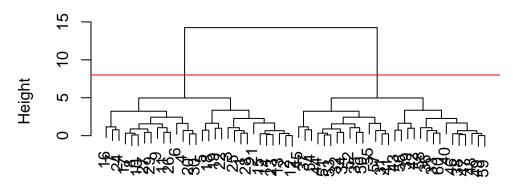

hclust(d = d)

 $\begin{array}{lll} \hbox{\tt Cluster method} & : & \hbox{\tt complete} \\ \hbox{\tt Distance} & : & \hbox{\tt euclidean} \end{array}$ 

Number of objects: 60

```
plot(hc)
abline(h=8, col="red")
```

# **Cluster Dendrogram**

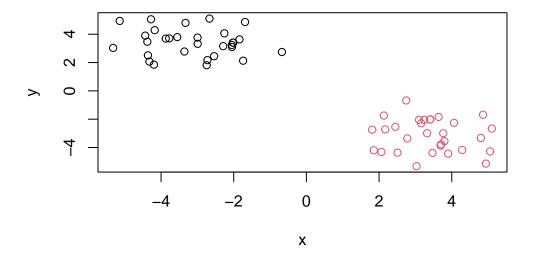

d hclust (\*, "complete")

I can get my cluster membership vector by "cutting the tree" with the  ${\tt cutree}$ () function like so:

```
grps <- cutree(hc, h=8)
grps</pre>
```

Can you plot z colored by our hclust results:

```
plot(z, col=grps)
```

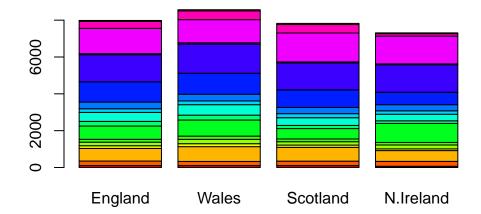

## $\#\#\mathrm{PCA}$ of UK food data

Read data from the UK on food consumption in different parts of the UK

```
url <- "https://tinyurl.com/UK-foods"
x <- read.csv(url, row.names=1)
head(x)</pre>
```

	England	Wales	${\tt Scotland}$	${\tt N.Ireland}$
Cheese	105	103	103	66
Carcass_meat	245	227	242	267
Other_meat	685	803	750	586
Fish	147	160	122	93
Fats_and_oils	193	235	184	209
Sugars	156	175	147	139

```
barplot(as.matrix(x), beside=F, col=rainbow(nrow(x)))
```

A so-called "Pairs" plot can be useful for small datasets like this one

pairs(x, col=rainbow(10), pch=16)

It is hard to see structure and trends in even this small data-set. How will we ever do this when we have big datasets with 1,000s or 10s of thousands of things we are measuring...

#### PCA to the resure

Let's see how PCA deals with this dataset. So main function in base R to do PCA is called prcomp()

```
pca <- prcomp( t(x) )
summary(pca)</pre>
```

#### Importance of components:

```
PC1 PC2 PC3 PC4
Standard deviation 324.1502 212.7478 73.87622 3.176e-14
Proportion of Variance 0.6744 0.2905 0.03503 0.000e+00
Cumulative Proportion 0.6744 0.9650 1.00000 1.000e+00
```

Let's see what is inside this pca object that we created from running prcomp()

```
attributes(pca)
```

#### \$names

```
[1] "sdev" "rotation" "center" "scale" "x"
```

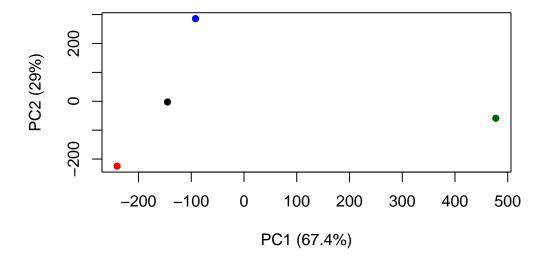

#### \$class

[1] "prcomp"

## pca\$x

```
PC1 PC2 PC3 PC4
England -144.99315 -2.532999 105.768945 -4.894696e-14
Wales -240.52915 -224.646925 -56.475555 5.700024e-13
Scotland -91.86934 286.081786 -44.415495 -7.460785e-13
N.Ireland 477.39164 -58.901862 -4.877895 2.321303e-13
```

```
plot(pca$x[,1], pca$x[,2],
  col=c("black", "red", "blue", "darkgreen"), pch=16,
  xlab="PC1 (67.4%)", ylab="PC2 (29%)")
```

# Lets focus on PC1 as it accounts for >90% of variance

```
par(mar=c(10, 3, 0.35, 0))
barplot( pca$rotation[,1], las=2 )
```
